ON THE RELATIONSHIP BETWEEN PROJECTIVE DISTRIBUTIVE LATTICES AND BOOLEAN ALGEBRAS

MIROSLAV PLOŠČICA

Abstract. The main result of this paper is the following theorem: If a projective Boolean algebra \( B \) is generated by its sublattice \( L \), then there is a projective distributive lattice \( D \) which is a sublattice of \( L \) and generates \( B \).

1. Preliminaries

The operations of Boolean algebras will be denoted by \( \land \) (meet), \( \lor \) (join), \( ' \) (complement), 0 (the least element) and 1 (the greatest element). If \( B \) is a Boolean algebra (we do not distinguish between the algebra and its underlying set) and \( H \subseteq B \), then \( \langle H \rangle \) denotes the subalgebra of \( B \) generated by \( H \). For Boolean algebras \( A, C \) we will write \( C \leq_{rc} A \) and say that \( C \) is relatively complete in \( A \), if \( C \) is a subalgebra of \( A \) and for every \( a \in A \) there exists the greatest \( c \in C \) with \( c \leq a \). We denote this element by \( a_C \). If \( C \leq_{rc} A \) then for each \( a \in A \) there exists the least \( c \in C \) with \( a \leq c \). This element will be denoted by \( a_C \). By \( C \leq_{rc \omega} A \) we understand that \( C \leq_{rc} A \) and \( A = \langle C \cup X \rangle \) for some countable set \( X \). The following statement is easy to prove (see [8]):

1.1. Lemma. Let \( A \) and \( C \) be subalgebras of a Boolean algebra \( B \).

(i) If \( A \leq_{rc} B \), \( A \subseteq C \subseteq B \), then \( A \leq_{rc} C \).

(ii) If \( A \leq_{rc} B \), \( x \in B \), then \( \langle A \cup \{x\} \rangle \leq_{rc} B \).

A chain \( \{A_\alpha \mid \alpha < \tau \} \) of Boolean algebras (where \( \tau \) is an arbitrary ordinal number) is said to be continuous if \( A_\lambda = \bigcup \{A_\alpha \mid \alpha < \lambda \} \) holds for each limit ordinal number \( \lambda < \tau \). For the sake of brevity, by a distributive lattice we understand in this paper a bounded lattice satisfying the well-known distributivity identities. Furthermore, all lattice homomorphisms are assumed to preserve the universal bounds. Analogically, saying that \( C \) is a sublattice of a distributive lattice \( D \) we mean that \( C \) is closed under \( \land \) and \( \lor \) and contains the universal bounds of \( D \). Free distributive lattices are the free objects in the category of bounded distributive lattices and 0, 1-preserving lattice homomorphisms. For every distributive lattice \( D \) there is unique (up to iso morphism) Boolean algebra \( B(D) \) that contains \( D \) as a sublattice and \( (D) = B(D) \). Each \( a \in B(D) \) can be expressed in the form \( a = a_0 + a_1 + \ldots + a_n \), where \( a_0, \ldots a_n \in D \), \( a_0 \leq a_1 \leq \ldots \leq a_n \) and \( + \) is the operation of symmetric difference (i. e. \( x + y = (x' \land y) \lor (x' \land y') \)). For every Boolean algebra \( B \), the set \( B \) with the operations \( +, \land \) is a ring. Further, we have identities \( a + a = 0 \), \( a \lor b = a + b + (a \land b) \), and \( a' = a + 1 \). Every homomorphism \( f : D_1 \rightarrow D_2 \) of

Typeset by \LaTeX
distributive lattices can be extended to a homomorphism \( f^* : B(D_1) \rightarrow B(D_2) \) of Boolean algebras. (See [4], ch.II.4.)

An object \( P \) of a category \( K \) is \( E \)-projective (where \( E \) is some class of epimorphisms) if, for every \( e \in E, e : A \rightarrow B \) and every morphism \( f : P \rightarrow A \), there exists a morphism \( g : P \rightarrow B \) with \( eg = f \). Injective objects are defined dually.

A projective Boolean algebra (distributive lattice) is an \( E \)-projective object of the category \( B \) of Boolean algebras (\( D \) of distributive lattices) and their homomorphisms, where \( E \) is the class of all surjective homomorphisms. Basic facts about projective Boolean algebras are summarized in the following assertion. For the proofs see [5] and [6]. Recall that an object \( A \) is a retract of \( B \) if there are morphisms \( f : A \rightarrow B, g : B \rightarrow A \) such that \( gf = id(A) \).

1.2. Theorem.

(i) A Boolean algebra is projective iff it is a retract of some free Boolean algebra.
(ii) Any free product of projective Boolean algebras is projective.
(iii) Every retract of a projective Boolean algebra is projective.
(iv) Every countable Boolean algebra is projective.

According to 1.2 every projective Boolean algebra is a subalgebra of a free Boolean algebra, hence it cannot contain an uncountable chain. We will use the following characterization of projective Boolean algebras proved by Koppelberg in [8]. Analogical result for Boolean topological spaces can be found in [7].

1.3. Theorem. Let \( A \) be a Boolean algebra. The following statements are equivalent:

(i) The Boolean algebra \( A \) is projective.
(ii) There exists a continuous chain \( \{A_\alpha \mid \alpha < \tau \} \) of subalgebras of \( A \) such that \( A_0 = \{0, 1\}, \bigcup \{A_\alpha \mid \alpha < \tau \} = A \) and \( A_\alpha \leq \text{rc}\omega A_{\alpha+1} \) holds for each \( \alpha \) with \( \alpha + 1 < \tau \).
(iii) There exists a family \( \mathcal{S} \) of subalgebras of \( A \) with the following properties:

\begin{enumerate}
    \item [(S1)] \( \{0, 1\} \in \mathcal{S} \);
    \item [(S2)] if \( S \in \mathcal{S} \) then \( S \leq \text{rc} A \);
    \item [(S3)] if \( C \subseteq \mathcal{S} \) is a non-empty chain under set inclusion then \( \bigcup C \in \mathcal{S} \);
    \item [(S4)] for each \( S \in \mathcal{S} \) and a countable subset \( X \) of \( A \), there is \( S' \in \mathcal{S} \) such that \( S \cup X \subseteq S' \) and \( S \leq \text{rc}\omega S' \).
\end{enumerate}

In the next theorem we summarize some facts about projective distributive lattices. Proofs of (i), (iii) and (iv) can be found in [1], [2], (ii) is contained in [3]. For a lattice \( L \), let \( J(L) \) and \( M(L) \) denote the set of all non-zero \( \lor \)-irreducibles and the set of all non-unit \( \land \)-irreducibles respectively.

1.4. Theorem.

(i) A distributive lattice is projective iff it is a retract of some free distributive lattice.
(ii) A distributive lattice \( D \) is projective iff it satisfies the following conditions:

\begin{enumerate}
    \item [(1)] \( J(D) \) is a \( \land \)-subsemilattice of \( D \);
    \item [(2)] both \( J(D) \) and \( M(D) \) generate \( D \);
    \item [(3)] for each \( a \in D \) there are two finite sets \( A(a) \subseteq \{d \in D \mid d \geq a\} \) and \( B(a) \subseteq \{d \in D \mid d \leq a\} \) such that \( A(a) \cap B(a) \neq \emptyset \) for every \( a \leq b \).
\end{enumerate}

(iii) A finite \( D \in D \) is projective iff it satisfies (1).
(iv) A countable \( D \in D \) is projective iff it satisfies (1) and (2).
The last four assertions of this section are technical lemmas about Boolean algebras. For the proof of 1.5 see [4], p.73.

1.5. Lemma (Sikorski’s extension criterion). Let $A$ and $B$ be Boolean algebras, $A$ generated by its subset $G$. Let $f$ be a map of $G$ into $B$. The map $f$ can be extended to a homomorphism of $A$ into $B$ iff, for arbitrary $x_1, x_2, \ldots, x_n, y_1, y_2, \ldots, y_m \in G$, the equality $x_1 \land \cdots \land x_n \land y_1 \land \cdots \land y_m = 0$ implies $f(x_1) \land \cdots \land f(x_n) \land f(y_m) = 0$.

1.6. Lemma. Let Boolean algebras $A$ and $C$ satisfy $C \leq_{re} A$ and let $a \in A, b \in C$. Then $(a \lor b)_C = a_C \lor b, (a \land b)_C = a_C \land b, (a \lor b)_C = a_C \lor b, (a \land b)_C = a_C \land b$.

Proof. We will show the first two equalities.

I. Denote $x = (a \lor b)_C, d = (a_C \lor b') \land x$. Clearly $a_C \lor b \leq x \leq a \lor b, a_C \leq d$. From $d \leq (a_C \lor b') \land (a \lor b) \leq a$ it follows that $d = a_C = \max \{c \in C | c \leq a \}$. We obtain $a_C \lor b = d \lor b = ((a_C \lor b') \land x) \lor b = x$. II. It holds that $a_C \land b \leq (a \land b)_C$, because $a \land b \geq a_C \land b \in C$. On the other hand, $(a \land b)_C \leq a_C$, $(a \land b)_C \leq b_C = b$, hence $(a \land b)_C \leq a_C \land b$. □

1.7. Lemma. Let Boolean algebras $A$ and $C$ satisfy $C \leq_{re} A$. Let $x_1, x_2, \ldots, x_n$ be distinct elements of $A$ such that $(x_i)_C \leq (x_{i+1})_C$ for each $i = 1, 2, \ldots, n - 1$. Let $M$ and $N$ be disjoint subsets of $\{1, 2, \ldots, n\}$. Denote $B = \{x_i \mid i \in M\} \cup \{x_i' \mid i \in N\}$. Then $(\bigwedge B)_C = \bigwedge \{x_C \mid x \in B\}$.

Proof. Let us denote $j = \min(M)$ and $k = \max(N)$, provided $M \neq \emptyset$ and $N \neq \emptyset$ respectively. In the case $M = N = \emptyset$ the assertion is evident. (We set $\bigwedge \emptyset = 1$.) If $M = \emptyset, N \neq \emptyset$ (the case $M \neq \emptyset, N = \emptyset$ is analogous), we have $(\bigwedge B)_C = (x_k')_C = \bigwedge \{x_C \mid x \in B\}$. Finally, assume $M, N \neq \emptyset$. We obtain $(\bigwedge B)_C = (x_j \land x_j')_C \leq (x_j)_C \land (x_j')_C = \bigwedge \{x_C \mid x \in B\}$. The inverse inequality is evident if $j < k$, because in this case $(x_j)_C \land (x_j')_C \leq (x_k)_C \land (x_k')_C = 0$. Now suppose that $j > k$. By 1.6 we have both $(x_j \land x'_k)_C \geq (x_j)_C \land (x'_k)_C$ and $(x_j \land x'_k)_C \geq (x_j)_C \land (x'_k)_C$. Since $(x_j)_C \lor (x'_k)_C \geq (x_j)_C \lor (x'_k)_C \geq (x_j)_C \lor (x'_k)_C = 1$, we get $(x_j \land x'_k)_C \geq ((x_j)_C \lor (x'_k)_C) \lor ((x_j)_C \lor (x'_k)_C) = (x_j)_C \land (x'_k)_C$. □

1.8. Lemma. Let a Boolean algebra $A$ be generated by its sub lattice $L$. Let $a, b \in L$. Then the interval $[a, b]$ of $A$ is generated (as a Boolean algebra) by its subset $[a, b] \cap L$.

Proof. The algebra $[a, b]$ is the homomorphic image of $A$ under the map $f(x) = (x \lor a) \land b$. Hence, it is generated by $f(L) \subseteq L \cap [a, b]$. □

2. The main results

2.1. Lemma. Let $D$ be a projective distributive lattice. Then $B(D)$ is a projective Boolean algebra.

Proof. Let $f : B_1 \longrightarrow B_2$ be an epimorphism of Boolean algebras (i.e. surjective homomorphism) and $g : B(D) \longrightarrow B_2$ an arbitrary homomorphism. Then we have the lattice homomorphism $g^* = g \mid D$ and, from the projectivity of $D$, a lattice homomorphism $h^* : D \longrightarrow B_1$ with $fh^* = g$, which can be extended to a homomorphism $h : B(D) \longrightarrow B_1 = B(B_1)$. The homomorphisms $fh$ and $g$ coincide on $D$, hence $fh = g$. □

Of course, a projective Boolean algebra can be generated by its non-projective sublattices as well. Notice that no Boolean algebra with more than two elements
is a projective distributive lattice. Now we are going to prove that if for a distributive lattice $L$, $B(L)$ is a projective Boolean algebra, then there exists a projective sublattice $D$ of $L$ with $B(D) = B(L)$.

2.2. Lemma. Let $A$ be a projective Boolean algebra generated by its sublattice $L$. Suppose that $\mathfrak{S}$ is a family of subalgebras of $A$ with the properties (S1)-(S4). Then for each $S \in \mathfrak{S}$ and countable $X \subseteq A$ there is a $S' \in \mathfrak{S}$ such that $S \cup X \subseteq S'$ and $S \leq_{\text{rel}} S' = (S \cup Y)$ for some countable $Y \subseteq L$.

Proof. We define an increasing chain $\{S_n \mid n < \omega\} \subseteq \mathfrak{S}$ such that $S \leq_{\text{rel}} S_i$ for each $i < \omega$. By (S4) there is $S_0 \in \mathfrak{S}$ such that $S \subseteq S_0$ and $S \leq_{\text{rel}} S_0$. Suppose now that we have defined $S_i \in \mathfrak{S}$ with $S_i = \{S \cup \{s_k \mid k < \omega\}\}$. For each $k$ there exists a finite set $Y_k \subseteq L$ such that $s_k \in \{Y_k\}$. Using (S4) we get $S_{i+1} \in \mathfrak{S}$ such that $S \cup Y_i \subseteq S_{i+1}$, $S \leq_{\text{rel}} S_{i+1}$. Moreover, the subalgebra of $S_{i+1}$ generated by $S \cup Y_i$ contains $S_i$. We set $S' = \{S_i \mid i < \omega\}$. We have $S' \in \mathfrak{S}$ (by (S3)), $S \leq_{\text{rel}} S'$, $X \subseteq S'$ and $S' = (S \cup Y)$, where $Y = \bigcup\{Y_i \mid i < \omega\}$. □

2.3. Lemma. Let $A$ be a projective Boolean algebra generated by its sublattice $L$. Then there exists a continuous chain $\{A_\alpha \mid \alpha < \tau\}$ of subalgebras of $A$ with the following properties:

(i) $A_0 = \{0, 1\}$;
(ii) $\bigcup\{A_\alpha \mid \alpha < \tau\} = A$;
(iii) for each $\alpha < \tau$ there is an $x \in L$ such that $A_\alpha \leq_{\text{rel}} A_{\alpha+1} = \{A_\alpha \cup \{x\}\}$;
(iv) for each $\alpha < \tau$ it holds that $A_\alpha = \langle A_\alpha \cap L \rangle$.

Proof. Let $\mathfrak{S}$ be a family of subalgebras of $A$ with the properties (S1)-(S4). First we construct a continuous chain $\{B_\alpha \mid \alpha < \lambda\} \subseteq \mathfrak{S}$ satisfying (i), (ii), (iv) and (iii') for each $\alpha < \gamma$ there is a countable $Y \subseteq L$ with $B_\alpha \leq_{\text{rel}} B_{\alpha+1} = \{B_\alpha \cup Y\}$.

We proceed by induction. Let us set $B_0 = \{0, 1\}$ and suppose that we have a chain $\{B_\alpha \mid \alpha < \lambda\} \subseteq \mathfrak{S}$. If $\bigcup\{B_\alpha \mid \alpha < \lambda\} = A$, we can set $\gamma = \lambda$. Otherwise we have $x \in A \setminus \bigcup\{B_\alpha \mid \alpha < \lambda\}$. For limit $\lambda$ we set $B_\lambda = \bigcup\{B_\alpha \mid \alpha < \lambda\} \subseteq \mathfrak{S}$. For $\lambda = \beta + 2$ and $\beta$ yields $B_\lambda \in \mathfrak{S}$ and a countable $Y \subseteq L$ with $B_\beta \cup \{x\} \subseteq B_\beta$ and $B_\beta \leq_{\text{rel}} B_\lambda = \{B_\beta \cup Y\}$. It is clear that the chain $\{B_\alpha \mid \alpha < \gamma\}$ has the desirable properties. Now we get the chain $\{A_\alpha \mid \alpha < \tau\}$ by inserting the algebras $\{B_\alpha \cup \{y_1\}\}$, $\{B_\alpha \cup \{y_1, y_2\}\}$, ..., (where $Y = \{y_i \mid i < \omega\} \subseteq L$, $B_{\alpha+1} = \{B_\alpha \cup Y\}$) between $B_\alpha$ and $B_{\alpha+1}$. Validity of (i), (ii) and (iv) is evident, (iii) follows from (iii’) and 1.1. □

2.4. Lemma. Let $x, a_0, a_1, \ldots, a_{2n}$ be elements of a Boolean algebra $A$ such that $x \geq a_0 + a_1 + \cdots + a_{2n}$, $a_0 \leq \cdots \leq a_{2n}$. Then $x \in \langle Y \rangle$, where $Y = \{a_0, a_2, a_4, \ldots, a_{2n}, (x \wedge a_{2n}) \vee a_{2n-1} \vee a_{2n-2} \vee \ldots, (x \wedge a_1) \vee a_0\}$.

Proof. Since $x$ is the complement of $a_{2n}$ in the interval $[x \wedge a_{2n}, x \vee a_{2n}]$, it suffices to prove that $x \wedge a_{2n} \in \langle Y \rangle$. By induction we show that $x \wedge a_i \in \langle Y \rangle$ for each $i = 0, 1, \ldots, 2n$.

We have $x \wedge a_0 \geq (a_0 + \cdots + a_{2n}) \wedge a_0 = a_0 + a_0 + \cdots + a_0 = a_0$, hence $x \wedge a_0 = a_0$, $x \wedge a_0 \in \langle Y \rangle$. Suppose now that $x \wedge a_{k-1} \in \langle Y \rangle$, $k \leq 2n$.

I. If $k$ is odd, then $x \wedge a_k$ is the complement of $a_{k-1}$ in the interval $[x \wedge a_{k-1}, (x \wedge a_k) \vee a_{k-1}]$ and $x \wedge a_{k-1} \in \langle Y \rangle$ implies that $x \wedge a_k \in \langle Y \rangle$.

II. If $k$ is even, we get $a_k \geq a_{k-1} \vee (x \wedge a_k) \geq a_{k-1} \vee ((a_0 + \cdots + a_{2n}) \wedge a_k) = a_{k-1} \vee (a_0 + \cdots + a_k) = a_{k-1} + a_0 + a_0 + \cdots + a_k + a_0 + a_1 + \cdots + a_{k-2} + a_{k-1} = a_k$.

Hence, $x \wedge a_k$ is the complement of $a_{k-1}$ in $[x \wedge a_{k-1}, a_k]$, $x \wedge a_k \in \langle Y \rangle$. □
2.5. Lemma. Let \( x, b_0, b_1, \ldots, b_{2n-1} \) be elements of a Boolean algebra \( A \) such that 
\[ x \leq b_0 + \cdots + b_{2n-1}, \quad b_0, \ldots, b_{2n-1} \leq b_{2n-1}. \]
Then \( x \in \langle Y \rangle \), where \( Y = \{b_0, \ldots, b_{2n-1}, (x \wedge b_1) \vee b_0, \ldots, (x \wedge b_{2n-1}) \vee b_{2n-2}\} \).

Proof. We have \( x' \geq (b_0 + \cdots + b_{2n-1})' = b_{2n-1} + \cdots + b_0 + 1 \). Now 2.4 yields that 
\[ x' \in \{(b_0', \ldots, b_{2n-1}', (x' \wedge b_0') \vee b_1', \ldots, (x' \wedge b_{2n-2}') \vee b_{2n-1}'\} = \langle Y \rangle. \]

\[ \square \]

2.6. Lemma. Let \( K \) and \( L \) be sublattices of Boolean algebras \( C \) and \( A \) respectively, such that \( C = \langle K \rangle \), \( A = \langle L \rangle \), \( C \leq_{re} A \) and \( A = \langle C \cup \{x\} \rangle \) for some \( x \in L \). Then there exist \( x_1, x_2, \ldots, x_m \in L \) with the properties

\[ (i) \quad (x_i)_C, (x_i)_C \subseteq K \quad \text{for each} \quad i = 1, 2, \ldots, m; \]
\[ (ii) \quad (x_i)' \subseteq (x_j)_C \quad \text{for each} \quad i < j; \]
\[ (iii) \quad A = \langle C \cup \{x_1, \ldots, x_m\} \rangle. \]

Proof. Let \( x_C = a_0 + \cdots + a_k \), where \( a_0, \ldots, a_k \in K \), \( a_0 \leq \cdots \leq a_k \). We can suppose that \( k = 2n \) otherwise we add 0 to the sum. By 2.4 we have \( A = \langle C \cup \{y_0, \ldots, y_n\} \rangle \), where \( y_n = x \vee a_{2n}, y_i = (x \wedge a_{2i+1}) \vee a_{2i} \) for \( i = 0, \ldots, n - 1 \). From 1.6 we get \( (y_i)_C = ((a_0 + \cdots + a_{2n}) \wedge a_{2i+1}) \vee a_{2i} = a_{2i} \). This holds also for \( i = n \). Element \( y_i \) \( (i = 0, \ldots, m - 1) \) belongs to the interval \( I_i = [a_{2i}, a_{2i+1}], y_i \in I_i = [a_{2i}, 1] \).
By 1.8, each \( I_i \) is, as a Boolean algebra, generated by \( I_i \cap K \). Clearly \((y_i)_C \subseteq I_i \), hence \((y_i)_C = (a_0 \ast \cdots \ast a_q) \), where \( a_0, \ldots, a_q \in I_i \cap K \), \( b_0 \leq \cdots \leq b_q \) and \( s \) is the addition in the algebra \( I_i \). We can suppose that \( q = 2p - 1 \). Now 2.5 yields that 
\[ y_i \in \langle C \cup \{y_1, \ldots, y_{2p}\} \rangle \quad \text{where} \quad y_{ij} = (y_i \wedge b_{2j-1}) \vee b_{2j-2}. \]
We have \((y_{ij})_C = (a_2i \ast b_{2j-1}) \vee b_{2j-2} \in K \) and \((y_{ij})_C = ((b_0 \ast \cdots \ast b_q) \wedge b_{2j-1}) \vee b_{2j-2} \in K \). The set \( \{x_1, \ldots, x_m\} \) will consist of all elements \( y_{ij} \).

\[ \square \]

2.7. Theorem. Let a projective Boolean algebra \( A \) be generated by its sublattice \( L \). Then there exists a projective distributivesublattice \( D \) of \( L \) generating the algebra \( A \).

Proof. Let \( \{A_\alpha \mid x < \tau \} \) be the chain of subalgebras of \( A \) constructed in 2.3. By induction we find a sequence \( \{F_\alpha \mid x < \tau \} \) of free Boolean algebras \( (F_\alpha \) with the free generating set \( M_\alpha \) \) and two sequences \( \{f_\alpha \mid x < \tau \} \) and \( \{e_\alpha \mid x < \tau \} \) of homomorphisms \( f_\alpha : F_\alpha \rightarrow A_\alpha, e_\alpha : A_\alpha \rightarrow F_\alpha \) with the following properties:

\[ (i) \quad f_\alpha e_\alpha = id(A_\alpha), \quad f_\alpha (M_\alpha) \subseteq L, \quad e_\alpha (f_\alpha (D_\alpha)) \subseteq D_\alpha, \quad \text{for each} \quad \alpha < \tau, \quad \text{where} \quad D_\alpha \]
\[ \quad \text{is the lattice generated by} \quad M_\alpha \quad \text{in} \quad F_\alpha; \]
\[ (ii) \quad M_\alpha \subseteq M_\beta, \quad f_\alpha \subseteq f_\beta, \quad e_\alpha \subseteq e_\beta, \quad \text{for each} \quad \alpha < \beta < \tau. \]

We set \( F_0 = \{0, 1\}, M_0 = 0 \) and define \( e_0 \) and \( f_0 \) by the obvious way. Let us suppose that we have constructed \( F_\alpha, e_\alpha, f_\alpha \) for all \( \alpha < \lambda < \tau \).

Let \( \lambda \) be a non-limit ordinal, \( \lambda = \beta + \tau \). Then we have \( A_\beta \leq_{re} A_\lambda = \langle A_\beta \cup \{x\} \rangle \) for some \( x \in L \cap A_\lambda, A_\lambda = \langle L \cap A_\lambda \rangle, A_\beta = \langle f_\beta (D_\alpha) \rangle \).

Let \( x_1, \ldots, x_m \in L \cap A_\lambda \) with the properties (i)-(iii) of 2.6. Take an arbitrary set \( Z = \{z_1, \ldots, z_m\} \) of the cardinality \( m \) with \( Z \cap A_\beta = \emptyset \). Let \( F_\lambda \supseteq F_\beta \) be the free Boolean algebra with the free generating set \( M_\lambda = M_\beta \cup Z \).
Let \( f_\lambda : F_\lambda \rightarrow A_\lambda \) be the homomorphism uniquely determined by the conditions \( f_\lambda \upharpoonright F_\beta = f_\beta \) and \( f_\lambda (z_i) = z_i \). Clearly \( f_\lambda (M_\lambda) \subseteq L \).

Using 1.5 we show that there exists a homomorphism \( e_\lambda : A_\lambda \rightarrow F_\lambda \) with \( e_\lambda \subseteq e_\beta \) and \( e_\lambda (x_1) = (z_1 \wedge e_\beta (b_1)) \vee e_\beta (a_1) \) \( (i = 1, \ldots, m) \), where \( a_1 = (x_1)_C, b_1 = (x_1)_C \). Suppose that \( Y = \{y_1, \ldots, y_n\} \subseteq A_\beta \cup \{x_1, \ldots, x_m, x'_1, \ldots, x'_m\} \).
\[ \text{We have to verify that} \quad d = \lambda \left[ \{e_\lambda (y_k) \mid y_k \in A_\beta \cup \{x_1, \ldots, x_m\} \} \wedge \{e_\lambda (y_k') \mid y_k' \in \{x'_1, \ldots, x'_m\} \} \right] = 0. \]
such $k$, by 1.6 and 1.7 we obtain that $0 = (\bigwedge Y)^C = \bigwedge\{(y_k)^C | y_k \in Y\}$. Since $e_\beta$ is an homomorphism, we have $0 = e_\beta(\bigwedge\{(y_k)^C | y_k \in Y\}) = \bigwedge\{e_\beta((y_k)^C) | y_k \in Y\} \geq d$. Thus, there is a homomorphism $e_\lambda$ fulfilling the above conditions. From $a_i, b_i \in f_\beta(D_\beta)$ and $e_\beta(f_\beta(D_\beta)) \subseteq D_\beta \subseteq D_\lambda$ we deduce that $e_\lambda(f_\lambda(z_i)) = (z_i \wedge e_\beta(b_i)) \vee e_\beta(a_i) \in D_\lambda$, hence $e_\lambda(f_\lambda(D_\lambda)) \subseteq D_\lambda$. Further, $f_\lambda(e_\lambda(x_i)) = f_\lambda((z_i \wedge e_\beta(b_i)) \vee e_\beta(a_i)) = (f_\lambda(z_i) \wedge b_i) \vee a_i = x_i$, hence $f_\lambda e_\lambda$ is the identity on a generating set, which implies that $f_\lambda e_\lambda = id(A_\lambda)$.

II. Let $\lambda$ be a limit ordinal. Let us set $M_\lambda = \bigcup\{M_\alpha | \alpha < \lambda\}$, $F_\lambda = \bigcup\{F_\alpha | \alpha < \lambda\}$. Validity of (i) and (ii) is evident.

Finally, set $D = \bigcup\{f(D_\alpha) | \alpha < \tau\}$, $f = \bigcup\{f_\alpha | \alpha < \tau\}$, $e = \bigcup\{e_\alpha | \alpha < \tau\}$. It is clear that $D \subseteq L$ and $\langle D \rangle = A$. Moreover, $D$ is a retract of the free distributive lattice $D_\tau = \bigcup\{D_\alpha | \alpha < \tau\}$ via $e \downarrow D$ and $f \uparrow D_\tau$. □

In particular, every projective Boolean algebra is generated by some of its projective distributive sublattices.

We can also formulate the consequence of 2.7 for ordered topological spaces, using the Priestley duality (see [9]). By this duality, projective Boolean algebras are associated with injective Boolean spaces (also called Dugundji spaces), i.e. retracts of a two element discrete space. Duals of projective distributive lattices are injective Priestley spaces (with respect to the class of all embeddings), i.e. retracts of powers of a two element chain.

2.8. Corollary. If the topology of a Priestley space $P$ is injective, then we can extend the ordering on $P$ in such a way that we get an injective Priestley space.

Finally, let us present one problem. Every free distributive lattice is a free product of three element lattices (i.e. free distributive lattices with one generator). Projective distributive lattices are just retracts of such free products. Free products of arbitrary finite (or countable) distributive lattices need not be projective, but they still generate projective Boolean algebras. The question now arises, whether the converse of this is true.

2.9. Problem. Let a distributive lattice $D$ generate a projective Boolean algebra $B(D)$. Is $D$ a retract of the free product of some finite (or countable) distributive lattices?
